## What is a Data Structure

Data Structure is a way of storing and organising data, so that it can be used efficiently.

As per the name indicates itself organise the data in memory.

It is a set of algorithms that we can use in any programming language to structure data.

## Classification Of DataStructure

©TopperWorld

### LINEAR DATA STRUCTURE

The arrangement of data in sequential manner is known as Linear Data Structure.

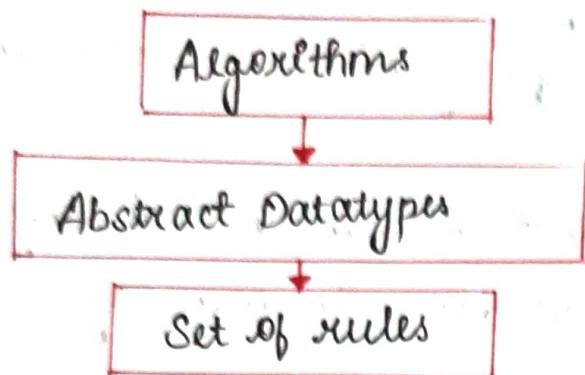

Examples: Arrays, Stacks, Queue, Linked List

### NON LINEAR DATA STRUCTURE:

When one element is connected do 'n' number of elements it is known as Non Linear Datastructure.

Examples: Trees, graphs

## ALGORITHMS AND ABSTRACT DATA TYPES

To structure the data in memory 'n' number of algorithms are proposed, and all these algorithms are known as Abstract Data Types

Abstract Data Types tells what is to be done  
Data Structure tells how is to be done

ADT gives us a blueprint while  
Data structure provides Implementation part

What is Data?

Data is defined as Elementary value / collection of values

Example :

Students name and students Id

## what is a Record?

Record is defined as collection of various data items

Example:

Student name, entity , address , course and marks can be grouped together to form **Record**

## What is a File?

File is a collection of various records of one type of entity

Example:

If there are 60 employees in a class then there will be 60 records related file where record contains info of employees

## What is attribute and Entity?

@TopperWorld

- Entity represents class of certain object
- Entity contains various attributes
- Each attribute represents property of entity

## What is the need of data Structure

As applicants are getting complexed and amount of data is increasing day by day

The following problem may arise:

Processor Speed: As the data is growing day by billions of files per entity. The processor may fail to deal with that amount of data.

Data Structures: consider an inventory size of 100 items in a store. If our application needs to traverse 100 items every time, results in slowing down process.

Multiple Requests: If thousands of users are searching data simultaneously on a web server, during that process.

To solve these problems, Data Structure is used.

Data is organised to form a data structure in such a way that all items are not required to be searched and require data can be searched instantly.

### Advantages of Data Structure

- Efficiency
- Reusability
- Abstraction

**Efficiency** - Data structure is a secure way of storing data on our system

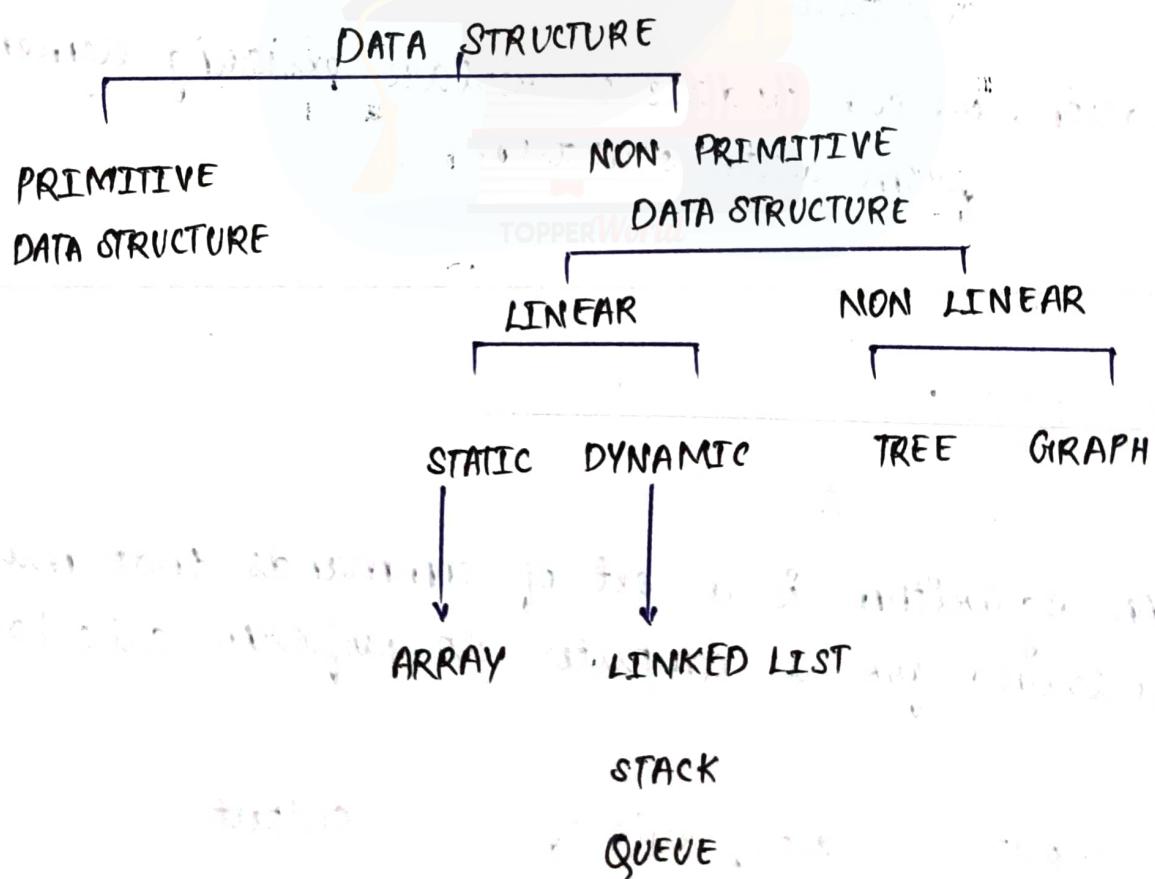

It helps us process data easily

**Reusable** - Data structures are reusable i.e. once we have implemented particular data structure, we can use it at any place.

**Abstraction** - It allows users to work with data structures without having to implementation details, which simplify programming

## DATA STRUCTURE CLASSIFICATION

©TopperWorld

## OPERATIONS ON DATA STRUCTURE:

Traversing - we can access an element of data structure at least once

Searching - we can easily search for data element in data structure

Sorting - we can sort elements either in ascending or descending order

Insertion - we can insert new data elements in data structure

Deletion - we can delete data elements from data structure

Updation - we can update or replace existing elements from data structure

## DATA STRUCTURE AND ALGORITHM

what is an Algorithm?

An algorithm is a set of commands that must be followed for a computer to perform calculations

Input	set of rules of obtain output from given input	Output
-------	--	--------

## CHARACTERISTICS OF AN ALGORITHM:

- Input - Algorithm take input data, which can be in various formats, such as number, text
- Processing - The algorithm processes the input data through series of logical and mathematical operations
- Output - After processing is complete, algorithm produces output.
- Efficiency - Aiming to accomplish tasks quickly
- Optimization - Optimize algorithm to make them fast and reliable.
- Implementation - Algorithm are implemented in various programming languages, enabling computers to execute them and produce outputs.

## ALGORITHM APPROACHES

BROTE FORCE ALGORITHM

DIVIDE AND CONQUER

GREEDY ALGORITHM

## ALGORITHM ANALYSIS

Algorithm analysis involves studying the efficiency and performance of algorithms in terms of their time complexity and space complexity.

By analyzing algorithms we can determine how they scale with input size and resources, helping us choose the most suitable algorithm for a specific problem.

## ASYMPTOTIC ANALYSIS:

The time required by an algorithm comes under three types

Worst case - It defines the input for which the algorithm takes a huge time.

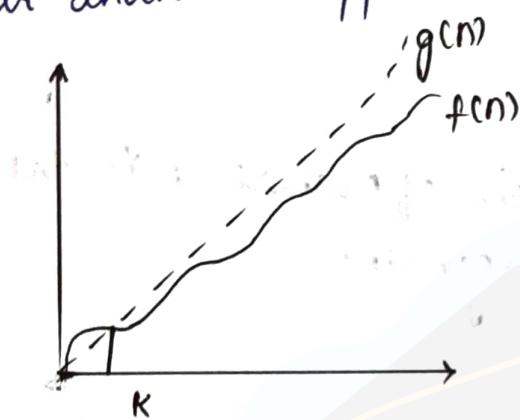

Average case - It takes average time for the program execution

Best case - It defines the input for which the algorithm takes the lowest time

**ASYMPTOTIC NOTATIONS:** used for calculating runtime complexity of an algorithm

① **Big oh notation ( $O$ ):** This measures the performance of an algorithm by simply providing the order of growth of function

This notation provides an upper bound on a function which ensures that function never grows faster than the upper bound

©TopperWorld

Example:

If  $f(n)$  and  $g(n)$  are two function defined for positive integer.

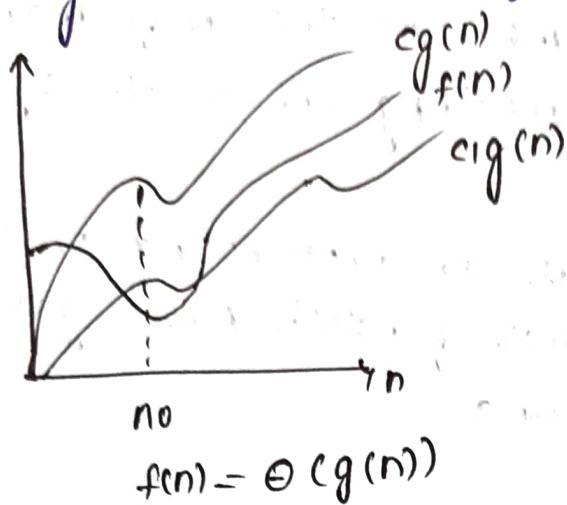

then  $f(n) = O(g(n))$  as  $f(n)$  is big oh of  $g(n)$  or  $g(n)$  is an order of  $f(n)$ . if there exists constant  $c$  and no such that

$$f(n) \leq c \cdot g(n) \text{ for all } n \geq n_0$$

② **Omega Notation ( $\Omega$ ):**

It is basically describes best case scenario which is opposite to big o notation. It is time formal

It is the formal way to represent lower bound of an algorithm's running time

Example:

Let  $f(n)$  and  $g(n)$  be functions of  $n$  where  $n$  is the steps required to execute programs

$$f(n) = \Theta g(n)$$

The above condition is satisfied only if when

$$c_1 \cdot g(n) \leq f(n) \leq c_2 \cdot g(n)$$

TOPPERWorld

### ③ Theta Notation ( $\Theta$ )

The Theta notation mainly describes average case scenarios

It represents realistic time complexity of an algorithm. Big theta is mainly used when the value of worst case and best case is same.

## POTINTER

Pointer is used to point the address of the value stored anywhere in the computer's memory.

### Pointer arithmetic

Four arithmetic operators can be used in pointers:  $++$ ,  $--$ ,  $+$ ,  $-$ .

### Array of pointers:

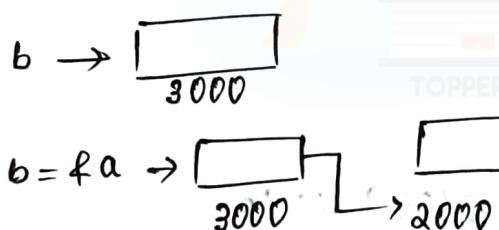

You can define array of held number of pointers.

### Pointer to pointer:

C allows you to have pointer on a pointer and so on.

© TopperWorld

## POINTER PROGRAM

```
#include <stdio.h>
int main()
{
    int a=5;
    int *b;
```

`b = &a;`

```
printf("value of a = %d\n", a);
printf("value of a = %d\n", (*d));
printf("value of a = %d\n", *b);
printf("value of a = %u\n", &a);
printf("address of a = %d\n", b);
printf("address of b = %u\n", &b);
printf("value of b = address of a = %u ; b);
```

`return 0;`

`}`

### OUTPUT

value of a = 5

value of a = 5

value of a = 3010494292

address of a = -1284473004

address of b = 301494296

value of b = address of a = 3010494292

### PROGRAM:

#### POINTER TO POINTER

```
#include<stdio.h>
int main()
{
    int a = 5;
    int *b;
```

```

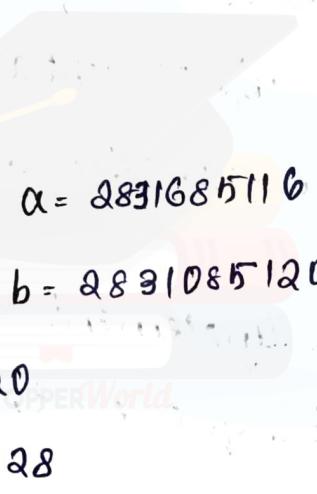

int **c;
b = &a;
c = &b;

printf("value of a=%d\n", a);
printf("value of b= address of a=%u\n", b);
printf("value of c=address of b=%u\n", c);
printf("value of b=%u\n", *c);
printf("address of c=%u\n", &c);

return 0;
}

```

**OUTPUT:**

 ©TopperWorld

value of a= 5

value of b= address of a= 2831685116

value of c= address of b= 2831085120

address of b= 2831585120

address of c= 2831685128

### STRUCTURE

A structure is a composite datatype that defines a grouped list of variables that are planned under one name in block of memory

## PROGRAM STRUCTURE

```
struct structure-name
{
    data-type member1;
    data-type member2;
    ;
    data-type member;
};
```

### ADVANTAGES OF STRUCTURE:

- It can hold variables of different datatype
- We can create objects containing different types
- It allows to re-use the datalayout across programs
- It is used to implement other data structure like linked list, queues, trees and graphs.

### PROGRAM:

#### HOW TO USE STRUCTURE IN PROGRAM:

```
#include <stdio.h>
#include <conio.h>
void main()
{
    struct employee
    {
        int id;
```

15

```
float salary;
int mobile;
};

struct employee e1, e2, e3;

printf("In Enter ids, salary, mobile no In");
scanf("%d %f %d", &e1.id, &e1.salary, &e1.mobile);
scanf("%d %f %d", &e2.id, &e2.salary, &e2.mobile);
scanf("%d %f %d", &e3.id, &e3.salary, &e3.mobile);

printf("In entered result");
printf("In %d %.f %.d ", e1.id, e1.salary, e1.mobile);
printf("In %d %.f %.d ", e2.id, e2.salary, e2.mobile);
printf("In %d %.f %.d ", e3.id, e3.salary, e3.mobile);

getch();
}
```

©TopperWorld

OUTPUT

GUESS THE OUTPUT

AND WRITE IT HERE

## ARRAYS:

Arrays are defined as collection of similar datatypes  
 Array is the simplest data structure where each element can be randomly accessed by using its index number

## ARRAY DECLARATION:

```
int arr[10]; char arr[10], float arr[5];
```

## PROGRAM WITHOUT USING ARRAY:

```
#include <stdio.h>
void main()
{
    int marks1;
    marks1=56;
    int marks_2 = 78; marks_3 = 89;
    float avg = (marks_1 + marks_2 + marks_3) / 3;
    printf("%f", avg);
}
```

## PROGRAM WITH USING ARRAY

```
#include <stdio.h>
void main()
{
    int marks[3] = {56, 78, 89};
    int i;
    float avg;
```

```

for( i=0; i<3; i++)
{
    avg = avg + marks[i];
}
printf("%d", avg);

```

## COMPLEXITY OF ARRAY OPERATION

### ① Time Complexity

Algorithm	Average case	worst case
Access	$O(1)$	$O(1)$
Search	$O(n)$	$O(n)$
insertion	$O(n)$	$O(n)$
Deletion	$O(n)$	$O(n)$

©TopperWorld

### ② space complexity

The array space complexity for worst case is  $O(n)$ .

## MEMORY ALLOCATION OF ARRAY

Each element in array represented by indexing

Indexing of array can be defined in three ways.

### 1. O(zero Based Indexing)

The first element of array will be  $arr[0]$

### 2. 1 (one-based Indexing)

The first element of array will be  $arr[1]$

### 3. n (n-based Indexing)

The first element of array can reside at random index

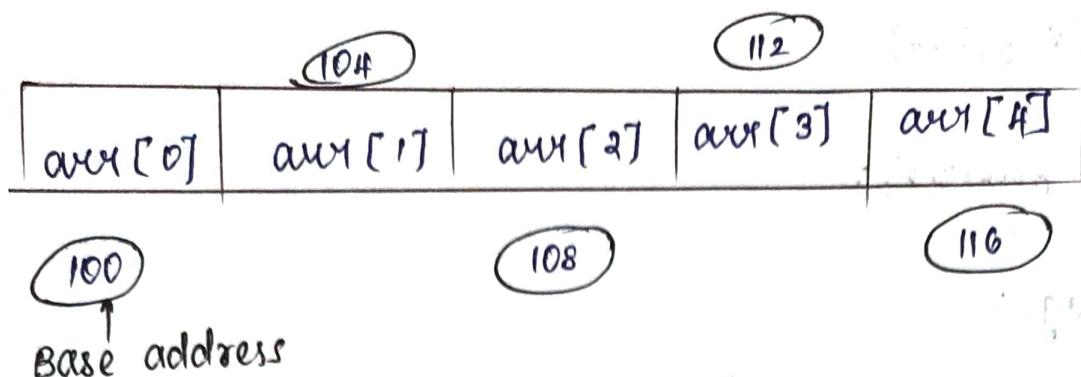

Figure : int arr[5]

### ACCESSING ELEMENTS OF ARRAY

To access any random element of an array we need to follow information

1. Base address of the array
2. size of an element in bytes
3. which type of indexing array follows.

Address of any element of 1D array can be calculated

Byte address of element  $A[i] = \text{base address} + \text{size} * (\text{First - index})$

Example:

In an array,  $A[-10+2]$ , Base address (BA) = 888, size of an element = 2 bytes, find location of  $A[-1]$

$$L(A[-1]) = 888 + [(-1) - (-10)] \times 2$$

$$\therefore L(A[-1]) = 888 + 18$$

$$\therefore \text{location of } A[-1] = 1017$$

## 2D ARRAY:

2D array can be defined as an array of arrays  
The 2D array is organised as an array of arrays.

How to declare 2D array

The syntax for declaration of two dimension array  
is

`int arr[max_rows][max_columns]`

However it produces data structures which looks like

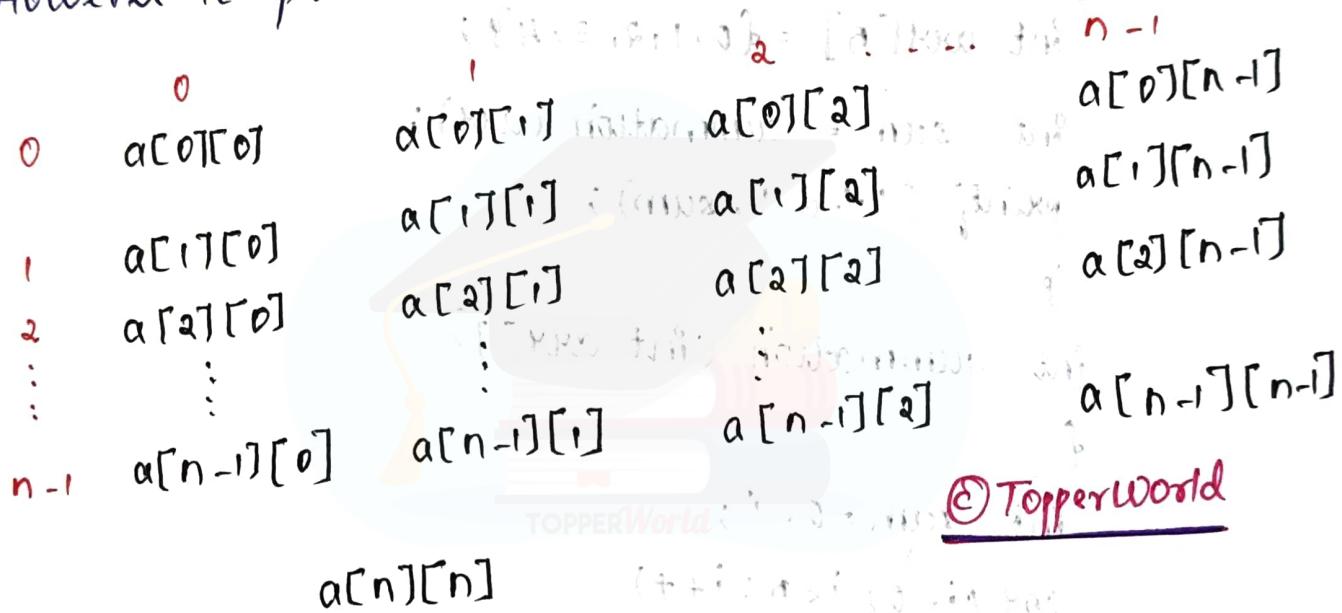

Figure :  $a[n][n]$

## HOW TO ACCESS DATA IN 2D ARRAY

Due to the fact that elements in 2D array can be randomly accessed

`int x = a[i][j];`

where  $i, j$  are rows and columns

## PASSING ARRAY TO FUNCTION:

The name of array represents the starting address or the address of first element of the array.

### PROGRAM

```
#include <stdio.h>
```

```
void summation(int []);
```

```
void main()
```

```
{ int arr[5] = {0,1,2,3,4};
```

```
int sum = summation(arr);
```

```
printf ("%d", sum);
```

```
int summation (int arr[])
```

```
{
```

```
int sum = 0, i;
```

```
for (i=0; i<5; i++)
```

```
{
```

```
sum = sum + arr[i];
```

```
return sum;
```

```
}
```

## INITIALISING 2D ARRAY:

The syntax to declare and initialize 2D array

```
int arr[2][2] = {{1, 2}, {3, 4}}
```

number of elements in 2D array = no. of rows \* no. of columns

## MAPPING 2D ARRAY TO 1D ARRAY

The size of two dimensional array is equal to multiplication of number of rows and number of columns present in array.

3x3 two dimensional array is shown.

@TopperWorld

			← COLUMN INDEX
			0      1      2
ROW INDEX	0	(0,0)    (0,1)	(0,2)
	1	(1,0)    (1,1)	(1,2)
	2	(2,0)    (2,1)	(2,2)

↑  
ROW INDEX

There are two main techniques of storing 2D array elements into memory

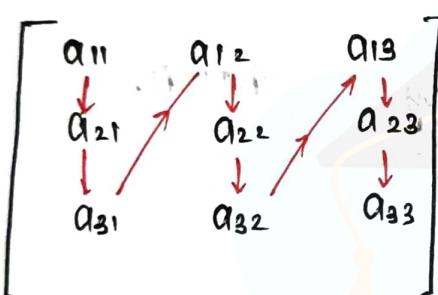

Row major ordering:

In row major ordering, all the rows of 2D array are stored into memory continuously.

Column major ordering

According to column major ordering, all columns of 2D array are stored in memory.

Calculating address of random elements of 2D array

① By row major order:

If array is declared  $a[m][n]$  where  $m$  is the number of rows while  $n$  is number of columns then address of element  $a[i][j]$  is calculated as

$$\text{Address}(a[i][j]) = B \cdot A + (i * n + j) * \text{size}$$

$B \cdot A$  is Base Address

2) By column major order:

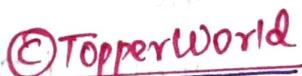

$$\text{Address } (a[i][j] \in j * m + i) * \text{size} + B \cdot A$$

### LINKED LIST

why there is a need of linked list?

If we declare an array of size. As we know that all the values of an array are stored in continuous manner, so the values of an array be stored in sequential fashion.

Then total memory space occupied by array would be  $3 * 4 = 12$  bytes

 **TopperWorld**

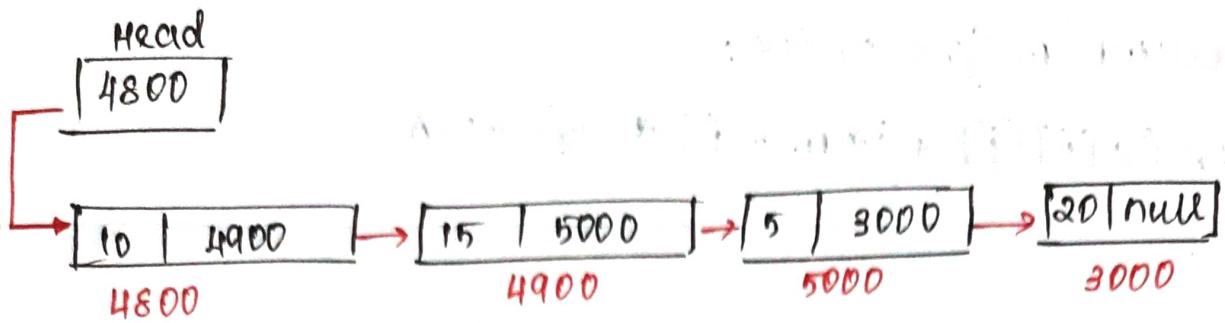

### DRAWBACKS OF USING ARRAY

we cannot insert more than 3 elements in above example because only 3 spaces are allocated by 3 elements.

In arrays, wastage of memory occurs.

### WHAT IS LINKED LIST?

A linked list is also a collection of elements, but the elements are not stored in consecutive location. It has two nodes. one is data, other is address part

## DECLARATION OF LINKED LIST:

In linked list, one is variable and second one is pointer variable. we can declare linked list by using user-defined data type called as structure.

```

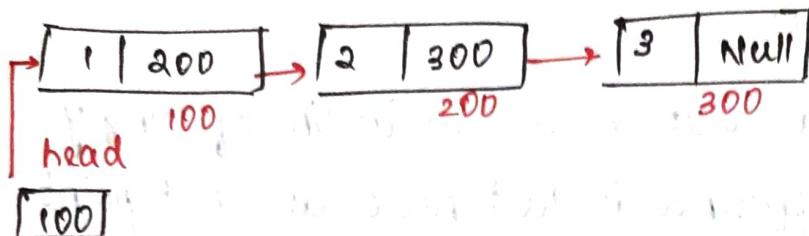

struct node
{
    int data;
    struct node next;
}
  
```

## TYPES OF LINKED LIST:

### 1) SINGLY LINKED LIST:

The singly linked list is most common which consist of data part and address part. The address part in the node is known as pointer.

Suppose we have three nodes and address of these three nodes are 100, 200 and 300:

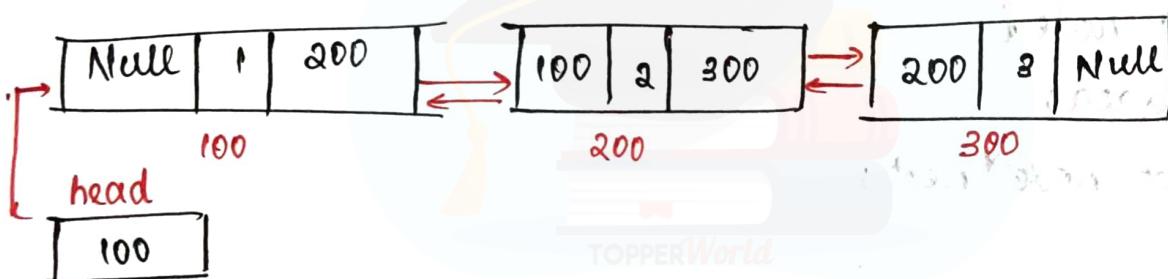

Null means its address part does not point to any node. The pointer that holds address of circular node is known as header pointer.

## 2) Doubly linked list:

As name suggests, the doubly linked list contains two pointers we define it in three parts. the data part and two address part

©TopperWorld

Representation of doubly linked list:

struct node {

int data;

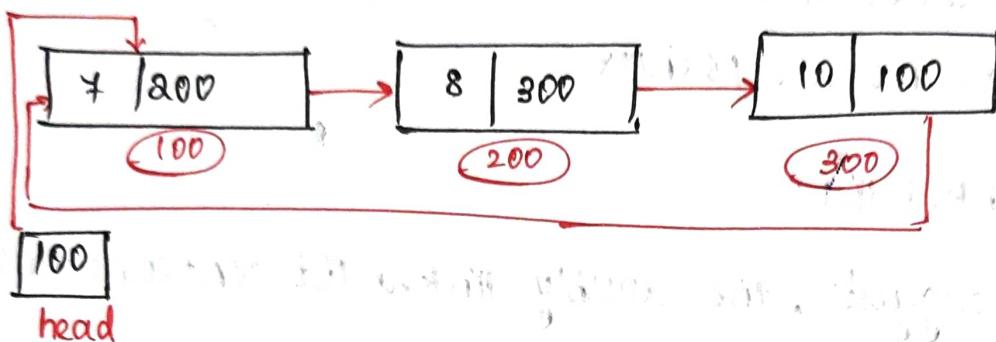

struct node\* next;

struct node\* prev;

}

### 3) CIRCULAR LINKED LIST:

A circular linked list is a variation of singly linked list. The only difference is last node does not point any node in a singly linked list.

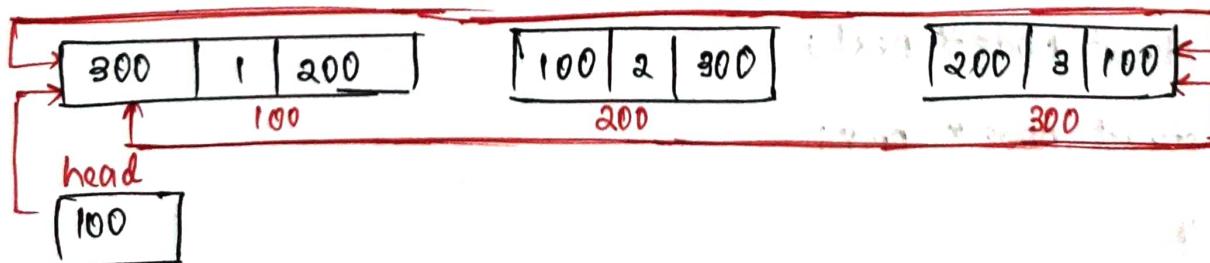

Representation of circular linked list:

```

struct node {
    int data;
    struct node* next;
}
  
```

### 4) Doubly circular linked list:

The doubly circular linked list has the features of both circular linked list and doubly linked list.

The last node is attached to first node and thus creates a circle.

The main difference is that doubly circular linked list does not contain null value in previous field of node.

Representation of doubly circular linked list:

```
struct node {
    int data;
    struct node* next;
}
```

```
struct node* prev;
```

Complexity.

TopperWorld

	Average	Worst	Space Complexity
singly linked list	Access $O(n)$	Search $O(n)$	Insertion $O(n)$
singly linked list	Access $O(n)$	Search $O(n)$	Insertion $O(1)$

## OPERATIONS ON SINGLY LINKED LIST:

### ① Node creation:

```
struct node
{
    int data;
    struct node* next;
};
```

```
struct node* head, *ptr;
ptr = (struct node*) malloc(sizeof(struct node))
```

### ② Insertion

1) Insertion at beginning: It involves inserting any elements at time while front of list. we just need a few link adjustment to make new node as head

2) Insertion at end of list: The new node can be inserted as the only node in list / it can be inserted as last one.

3) Insertion after specified node: we need to skip desired number of nodes in order to rereach node after which the new node will be inserted

### ② 3) Deletion and Traversing:

① Deletion at beginning: It just needs few adjustments in the node pointers.

② Deletion at end: Removing the node from end of list

③ Traversing: visiting each node of the list atleast once in order to perform some specific operation on it, for example printer data part of each node present in the list

(C) TopperWorld

Searching: In searching, we match each element of the list with the given elements. If elements is found on any of location of that elements. Ps returned otherwise null is returned.

## OPERATIONS ON DOUBLY LINKED LIST

### ① Node creation:

```
struct node{
```

```
    struct node* prev;
```

```
    int data;
```

```
    struct node* next;
```

```
y;
```

```
};
```

```
struct node* head;
```

## 2) Insertion

① Insertion at beginning: Adding the node into the linked list at the beginning

② Insertion at end: Adding the node into the linked list to the end.

## 3) Deletion and Traversing:

① Deletion at beginning: Removing the node from the beginning of the list

② Deletion at end: Removing the node from end of the list.

Traversing: visiting each node of the list atleast once in order to perform some specific operation like searching, sorting, display etc.

Searching: comparing each node data with the item to be searched and return location of item in the list if the item found else return null.

## Skip List:

What is a skip list?

skip list is used to store a linked list of elements or data with linked list. The one single step, it skip several elements of entire list.

## STRUCTURE OF SKIPLIST:

skip list is built in two layers: The lowest layer and the top layer. The lowest layer of the skip list is a common sorted linked list, and the top layers of the skip list are like an expression where elements are skipped.

## COMPLEXITY TABLE:

SNO	COMPLEXITY	AVERAGE CASE	WORST CASE
1	Access complexity	$O(\log n)$	$O(n)$
2	search complexity	$O(\log n)$	$O(n)$
3	delete	$O(\log n)$	$O(n)$
4	Insert	$O(\log n)$	$O(n \log n)$
5	space		<u>©TopperWorld</u>

## BASIC OPERATIONS AND ITS ALGORITHM:

① Insertion operation: It is used to add new node to particular location in a specific situation.

② Deletion operation: It is used to delete a node in a specific situation.

③ search operation: The search operation is used to search a particular node in a skip list.

## ALGORITHM OF INSERTION OPERATION:

Insertion ( $L$ , key)

local update [ $0 \dots \max\text{-level} + 1$ ]

$\alpha = L \rightarrow \text{header}$

for  $i = L \rightarrow \text{level down}$

while  $\alpha \rightarrow \text{forward}[i] \rightarrow \text{key forward}[i]$

update [ $i$ ] =  $\alpha$

$\alpha = \alpha \rightarrow \text{forward}[0]$

$lv1 = \text{random-level}()$

If  $lv1 > L \rightarrow \text{level}$  then

for  $i^o = L \rightarrow \text{level} + 1$  to  $lv1$  do

update [ $i$ ] =  $L \rightarrow \text{header}$

$L \rightarrow \text{level} = lv1$

$\alpha = \text{make node}(lv1, \text{key}, \text{value})$

for  $p = 0$  to  $\text{level}$  do

$\alpha \rightarrow \text{forward}[i] = \text{update}[i] \rightarrow \text{forward}[i]$

update [ $i$ ]  $\rightarrow$   $\text{forward}[i] = \alpha$ .

## ALGORITHM OF DELETION OPERATION:

Deletion ( $L$ , key)

local update [ $0 \dots \max\text{-level} + 1$ ]

$\alpha = L \rightarrow \text{header}$

for  $i = L \rightarrow \text{level down}$  0 to 90

while  $a \rightarrow \text{Forward}[i] \rightarrow \text{key forward}[i]$

update  $[i] = a$

$a = a \rightarrow \text{Forward}[0]$

if  $a \rightarrow \text{key} = \text{key}$  then

for  $i = 0$  to  $L \rightarrow \text{level}$  do

if update  $[i] \rightarrow \text{forward}[i] ? a$  then break

update  $[i] \rightarrow \text{forward}[i] \rightarrow \text{forward}[i]$

Free  $(a)$

while  $L \rightarrow \text{level} \neq 0$  and  $L - \text{header} \rightarrow \text{Forward}$

$[L \rightarrow \text{level}] = \text{NIL}$  do

$L \rightarrow \text{level} = L \Rightarrow \text{level} - 1$

## ALGORITHM OF SEARCHING OPERATION:

searching ( $L$ ,  $skey$ )

$a = L \rightarrow \text{header}$

loop invariant :  $a \rightarrow \text{key level down to } 0$  do

while  $a \rightarrow \text{Forward}[i] \rightarrow \text{key forward}[i]$

$a = a \rightarrow \text{Forward}[a]$

if  $a \rightarrow \text{key} = skey$  then return  $a \rightarrow \text{value}$

else return failure.

@TopperWorld

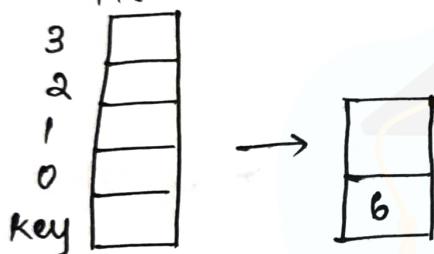

Example:

Create a skip list, we want to insert these following keys in empty skip list.

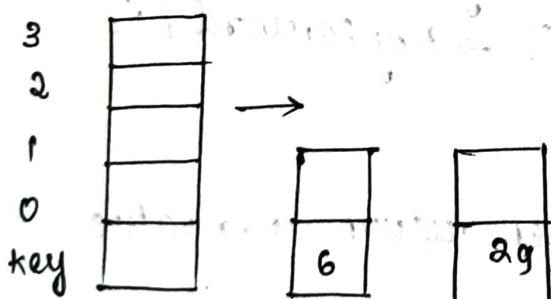

1. 6 with level 1
2. 2g with level 1
3. 2a with level 4
4. g with level 3
5. 17 with level 1
6. 4 with level 2

Solution: Insert 6 with level 1

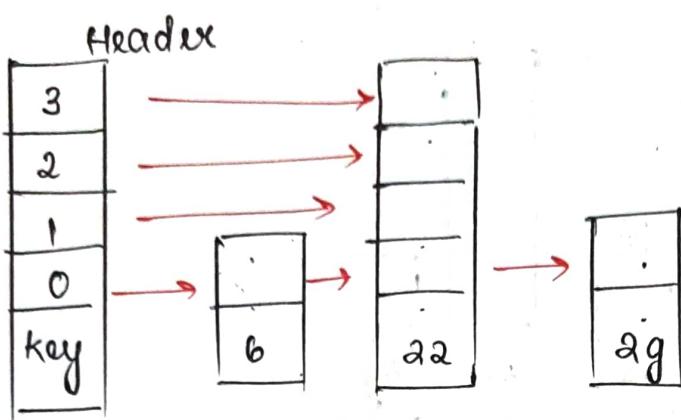

Header

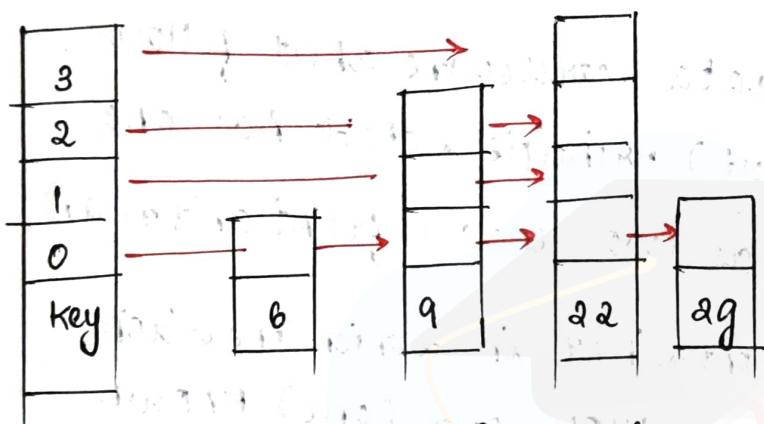

Step 2: Insert 2g with level 1

Step 3: Insert 22 with level 4

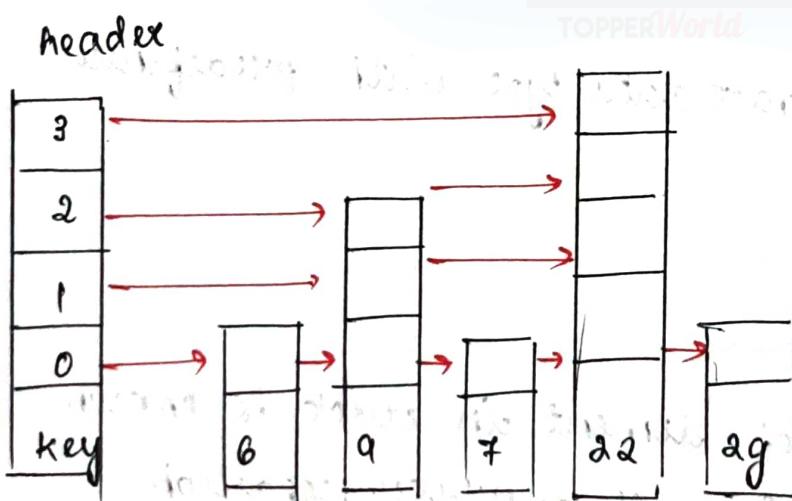

Step 4: Insert g with level 3

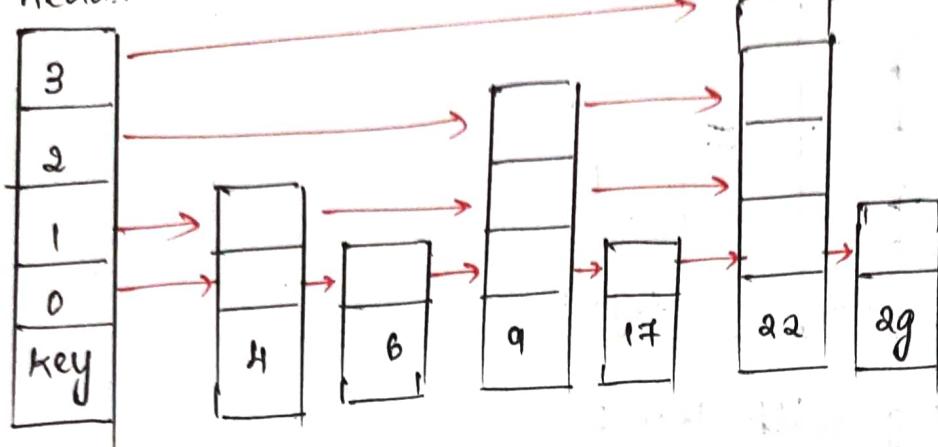

@TopperWorld

step 5: Insert 7 with level 1

step6: Insert 4 with level 2

header

### STACK:

stack is a linear data structure that follows LIFO (Last In First Out) principle, stack has one end, whereas queue has two ends (front and rear)

A stack is a container in which insertion and deletion can be done from end (one) known as top of stack.

A stack is abstract data type with predefined capacity.

### OPERATIONS OF STACK:

push() - insertion of element in stack is known as push. If stack is full overflow condition occurs.

- pop() Deletion of element from stack is known as pop operation. If stack is empty, underflow occurs.
- peek() It returns element at given index.
- count() It returns total number of count.
- change() It changes the element at a given position.
- display() It prints all the elements available.

### PUSH OPERATION:

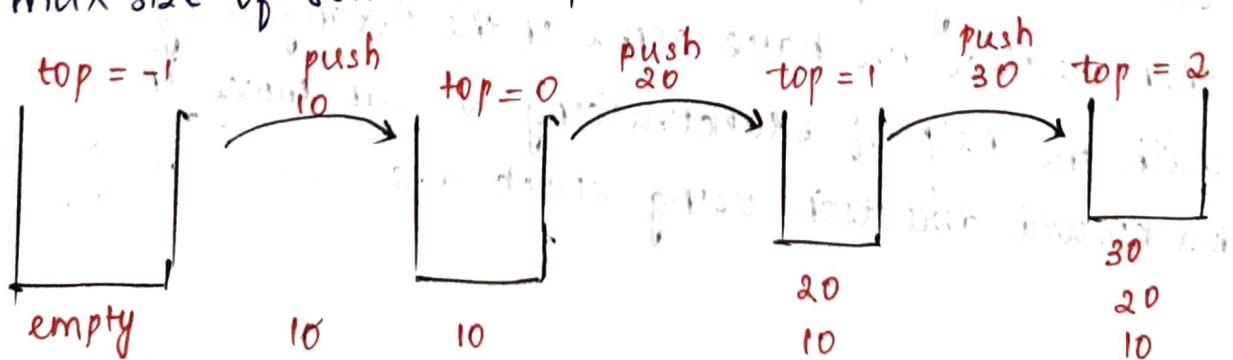

Before inserting element in stack, we check whether stack is full.

@TopperWorld

If stack is full and we try to insert, overflow condition occurs.

We set top value as -1. to check whether stack is empty.

The elements will be inserted until we reach max size of stack ie  $\text{top} = \text{top} + 1$ .

## POP OPERATION:

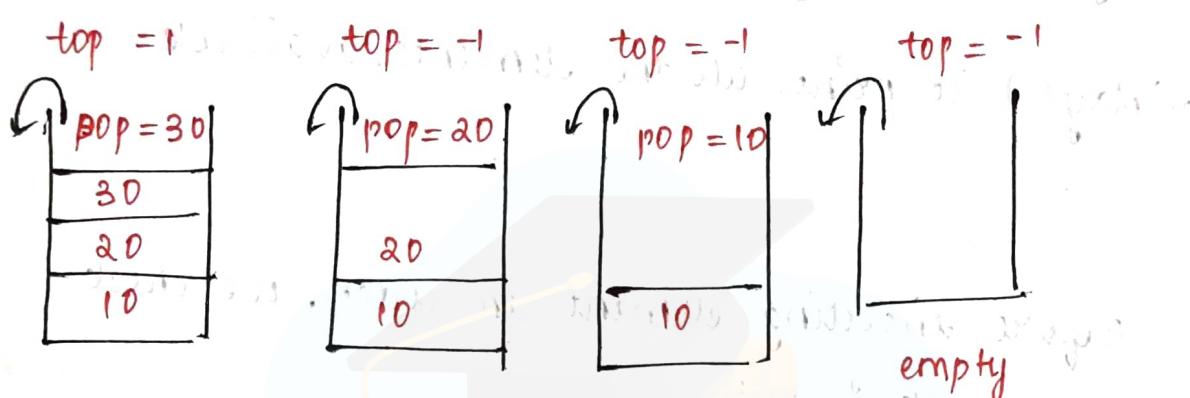

Before deleting we check whether stack is empty

If stack is empty, we try to delete elements, underflow condition occurs.

First access element which is pointed by top

Once top is performed, top is decremented by 1,

i.e.  $\text{top} = \text{top} - 1$

## APPLICATIONS OF STACK:

Recursion: The recursion is a method calling itself again and again.

Depth First search: This is implemented on a graph using stack d.s

Backtracking: If we move in forward direction & then realise we have come on the wrong way with the help of backtracking we can move in backward direction using stack d.s

4) Memory management: The stack manages the memory  
The memory is assigned in continuous memory blocks.

### Algorithm

#### Push operation

```
begin
    if top = n, stack is full
    top = top + 1
    stack(top) = item
end
```

Time complexity:  $O(1)$

#### pop operation

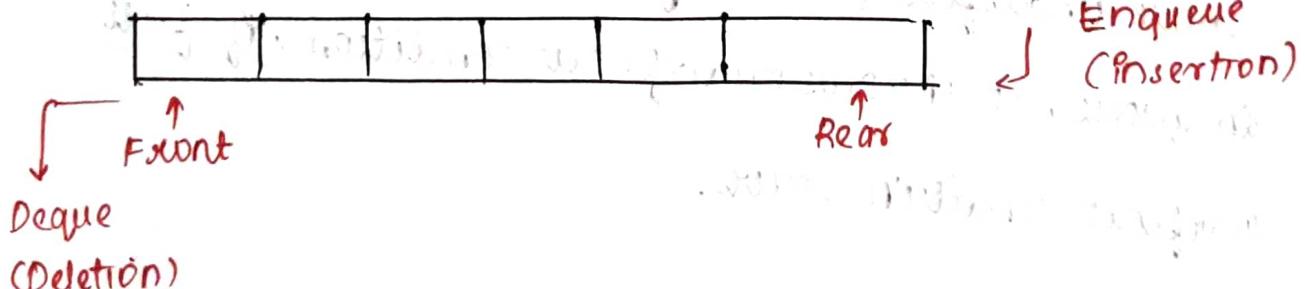

```
begin
    if top = 0, empty
    item = stack(top);
    top = top - 1;
end
```

Time complexity:  $O(1)$

### QUEUE:

### TOPPERWorld

A queue can be defined as ordered list which enables insert operations to be performed at one end called REAR and delete operations to be performed at another end called FRONT.  
Queue can be referred as to be first in first out.

## COMPLEXITY OF QUEUE:

Queue	Average Access $O(n)$	search $O(n)$	Deletion $O(1)$	insertion $O(1)$	space complexity worst $O(n)$
Queue	worst Access $O(n)$	search $O(n)$	Deletion $O(1)$	insertion $O(1)$	

## OPERATIONS ON QUEUE:

Enqueue: Enqueue is used to insert element at rear end of queue. It returns void.

Dequeue: Dequeue operations performs the deletion from front end of queue. The dequeue operation can also be designed to void.

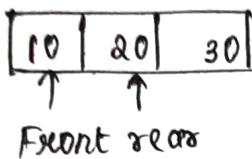

Peek: This returns element which is pointed by front pointer in the queue but does not delete it.

Queue overflow (Is Full): when queue is completely full then it shows overflow condition

Queue underflow (Is empty): when there is no element in queue, it throws underflow condition, if full overflow condition occurs.

## TYPES OF QUEUE:

Linear Queue: In linear queue, an insertion takes place from one end while deletion occurs from another end. It strictly follows FIFO rule. The linear queue can be represented as shown.

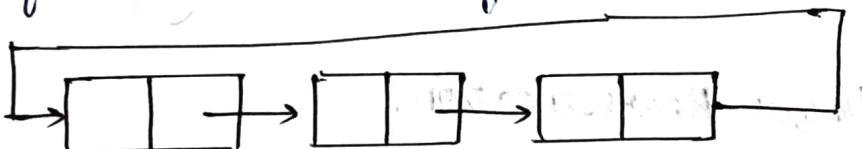

The elements are inserted from rear end, and if we insert more elements in queue, then rear values gets incremented on every insertion.

Drawback of linear queue is: insertion is done only from rear end.

©TopperWorld

## Circular Queue

In circular queue, the last element points to the first element making a circular link

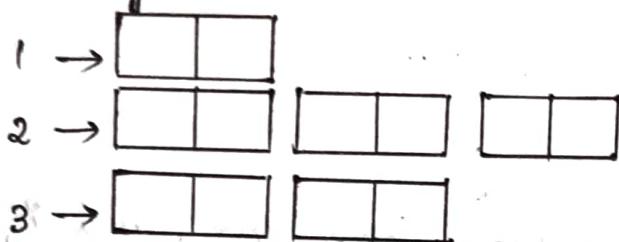

circular Queue Representation.

The main advantage of circular queue over a simple queue is better memory utilization. If the last position is full and first position is empty, we can insert in first position. This is not possible in simple queue.

## Priority Queue:

It is a type of queue served according to its priority. If elements with same priority occur, they are served according to their order in queue.

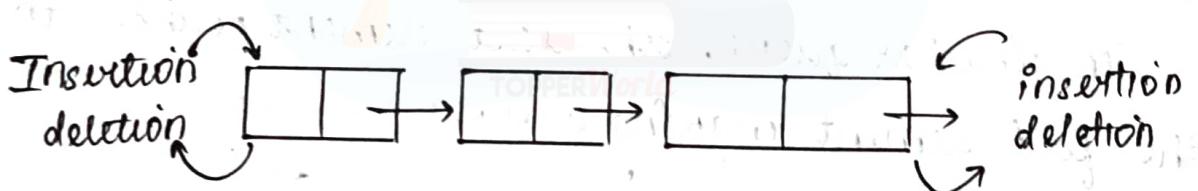

### Priority

## Priority Queue Representation

### Deque (Double Ended Queue)

In a double ended queue, insertion and removal of elements can be performed from either front or rear. It does not follow FIFO.

## Deque Representation:

### ALGORITHM TO INSERT ANY ELEMENT IN A QUEUE:

check if queue is already full by comparing rear to max - 1.

STEP 1: IF REAR = MAX - 1  
 WRITE OVERFLOW  
 GO TO STEP [END OF IF]

STEP 2: IF FRONT = -1 and REAR = -1  
 SET FRONT = REAR = 0  
 ELSE  
 SET REAR = REAR + 1 [END OF IF]

STEP 3: SET QUEUE [REAR] = NUM

STEP 4: EXIT

### ALGORITHM TO DELETE AN ELEMENT FROM QUEUE

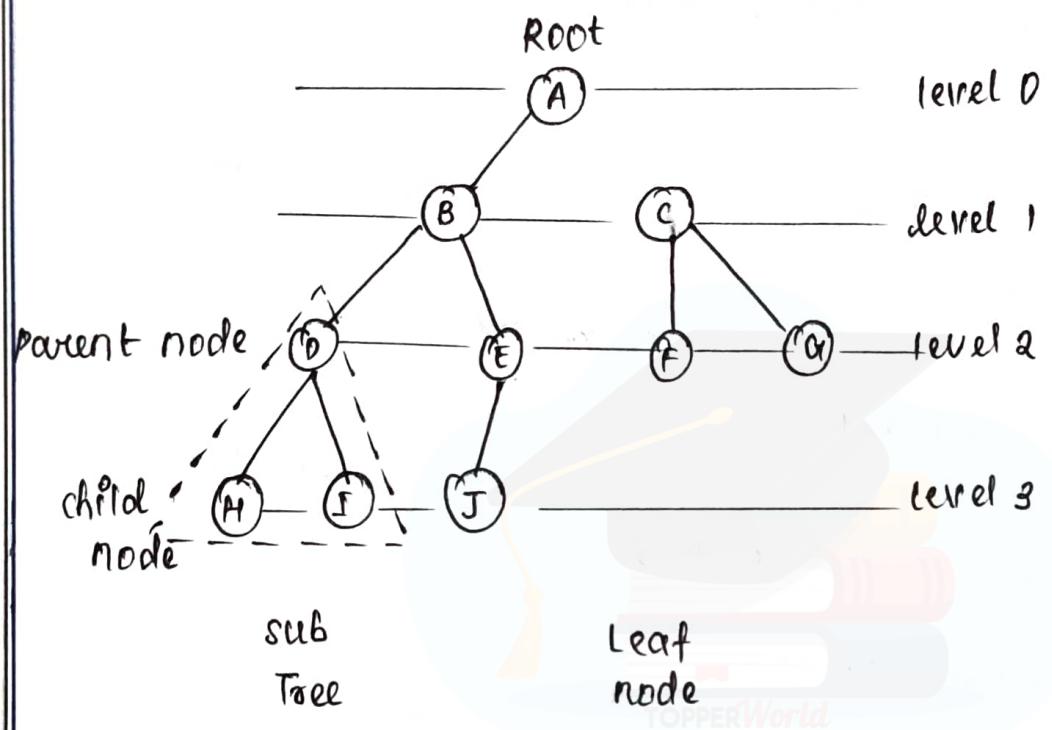

STEP 1: IF FRONT = -1 OR FRONT > REAR  
 WRITE UNDERFLOW  
 ELSE  
 SET VAL = QUEUE [FRONT]  
 SET FRONT = FRONT + 1  
 [END OF IF]

STEP 2: EXIT

## TREE:

A tree is a non linear abstract datatype with hierarchy based structure. It consists of nodes that are connected via links. The tree data structure stems from a single node called root node and has subtrees connected to root.

## IMPORTANT TERMS:

Following are the important terms with respect with Tree

**path:** Path refers to sequence of nodes along the edge of a tree

Root: The node at top of tree is called root.

Parent: Any node except root node has one edge upward to node called parent

Child: The node below the given node connected by its edge downward is called its child node.

Leaf: The node which does not have any child node is called leaf node

Subtree: Subtree represents descendants of node

Visiting visiting refers to checking the value of node when control is on node.

Traversing: Traversing means passing through nodes in specific order

levels: levels of a node represents the generation of a node. If root node is at level 0, then its next child node is at level 1. its grandchild is at level 2. and so on.

Keys: Key represents a value of a node based on which a search operation is to be carried out for a node.

## Types of Trees:

There are three types of trees:

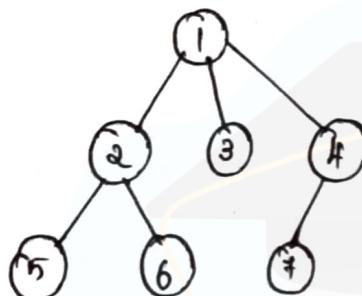

General Trees

Binary Trees

Binary search Trees.

### General Trees:

General Trees are unordered tree data structure where the root node has minimum 0 or maximum 'n' subtrees.

General Tree Data Structure

### Binary Trees:

Binary Trees are general trees in which the root node can only hold up to maximum 2 subtrees. left subtree and right subtree.

### Full Binary Tree:

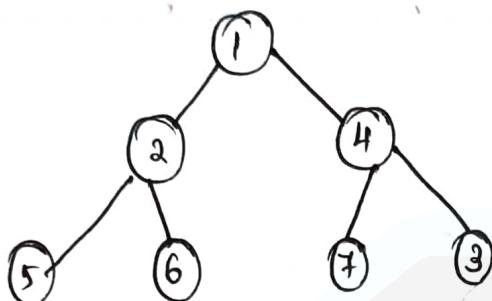

A full binary tree is a binary tree type where every node has either 0 or 2 child nodes.

## Complete Binary Tree:

A complete binary tree is a binary tree where all leaf nodes must be on same level.

## Perfect Binary Tree:

The leaf nodes are on same level and every node except leaf nodes have 2 children

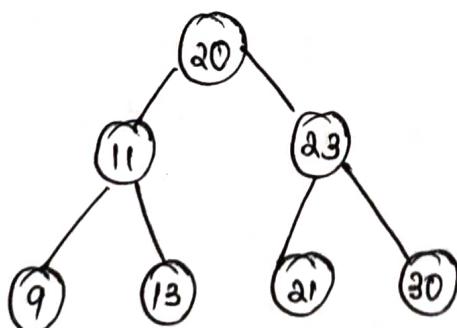

Binary Tree data structure

© TopperWorld

## Binary Search Tree

The data in binary search tree is always stored in such a way that the values in the left subtree are always less than values in root node and the values in the right subtree are always greater than values in root node.

Binary Search Tree Data Structure

Balanced Binary Search Tree:

consider a balanced binary search tree with 'm' as height of left subtree and 'n' as height of right subtree. If the value of  $(m-n)$  is equal to 0, 1, or -1, the tree is said to be Balanced Binary Search Tree.

There are various types of self-balancing binary search trees

AVL Trees

Red Black Trees

B Trees

B+ Trees

Splay Trees

Priority Search Trees

### GRAPH:

A graph can be defined as group of vertices and edges that are used to connect these vertices.

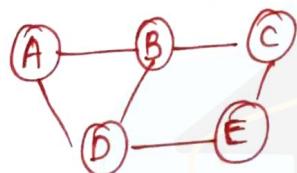

let us try to understand this through example:  
on facebook, everything is a node. That includes user, photo, album, event, group, page, comment, story.  
anything that has data is a node.

Example of graph data structure.

Directed and Undirected graph:

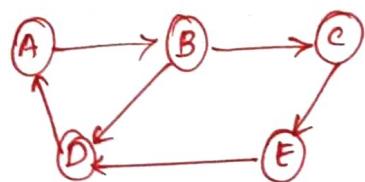

A graph can be directed or undirected. However in an undirected graph, edges are not associated with directions with them

© TopperWorld

Undirected graph

As the above figure edges are not attached with any of the directions

Directed graph

In the above figure, directed graph edges form an ordered pair.

## GRAPH TERMINOLOGY

**Path:** path can be defined as sequence of nodes that are followed in order to reach some terminal node  $v$  from initial node  $v$

**Closed Path:** A path will be called as closed if initial node is same as terminal node  $v_0 = v_N$ .

**Simple path:** If all nodes of graph are distinct with an expression  $v_0 = v_N$ , then such path is called as closed simple path

**Cycle:** A cycle is a path which has no repeated edges or vertices except first and last vertices.

**Connected graph:** A graph in which some path exists between every two vertices  $(u, v)$  in it.

There are no isolated nodes in connected graph.

**Complete graph:** A graph in which every node is connected with all other nodes. A complete graph contains  $\frac{n(n-1)}{2}$  edges where  $n$  is the number of nodes in graph.

**Weighted graph:** In this graph each node is assigned with some data such as length or width. The weight of an edge can be given as  $w(e)$  which must be positive ( $t$ ) value indicating cost of traversing edge

**Diagraph:** A diagraph is directed graph in which each edge is associated with some direction and traversing can be done only in specified direction

**Loop:** An edge that is associated with similar end points can be called as loop.

**Adjacent nodes:** If two nodes  $u$  and  $v$  are connected via an edge  $e$ , then nodes  $u$  and  $v$  are called as neighbours.

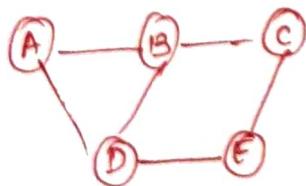

**Degree of a Node:** A degree of a node is a number of edges that are connected with that node. A node with degree 0 is called isolated

### GRAPH REPRESENTATION:

@TopperWorld

#### SEQUENTIAL Representation:

In this we use adjacent matrix to store mapping represented by vertices and edges. A graph having  $n$  vertices will have dimension  $n \times n$ .

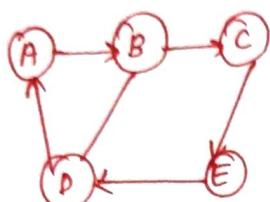

undirected graph.

	A	B	C	D	E
A	0	1	0	1	0
B	1	0	1	1	0
C	0	1	0	0	1
D	1	1	0	0	1
E	0	0	1	1	0

Adjacency matrix.

In the above figure, we can see mapping among vertices  $(A, B, C, D, E)$  is represented by using adjacency matrix which is shown in figure.

A directed graph and its adjacency matrix representation is shown in figure.

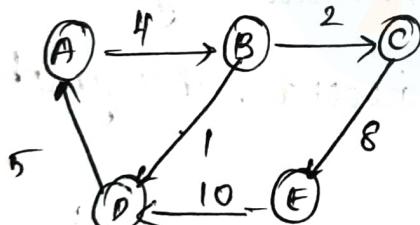

Directed graph

	A	B	C	D	E
A	0	1	0	0	0
B	0	0	1	1	0
C	0	0	0	0	1
D	1	0	0	0	0
E	0	0	0	1	0

Adjacency matrix

Representation of weighted directed graph is different. Instead of filling entry by 1, non zero entries of adjacency matrix are represented by weight of edges.

TopperWorld

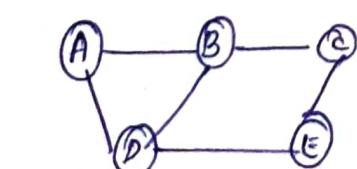

Weighted undirected graph

	A	B	C	D	E
A	0	4	0	0	0
B	0	0	2	1	0
C	0	0	0	0	8
D	5	0	0	0	0
E	0	0	10	10	0

Adjacency matrix

## ② linked representation:

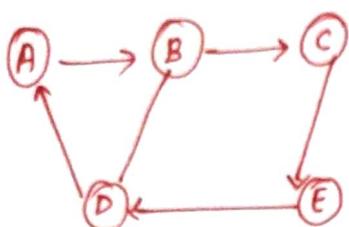

undirected graph

Adjacency list.

A $\rightarrow$ B	$\rightarrow$ D	x
B $\rightarrow$ A	$\rightarrow$ D	$\rightarrow$ C x
C $\rightarrow$ B	$\rightarrow$ E	x
D $\rightarrow$ A	$\rightarrow$ B	$\rightarrow$ E x
E $\rightarrow$ D	$\rightarrow$ C	

An adjacency list is maintained for each node present in graph, which stores node value and a pointer to next adjacent node to respective node.

Directed graph

$A \rightarrow B$	x
$B \rightarrow C$	x
$C \rightarrow E$	x
$D \rightarrow A$	x
$E \rightarrow D$	x

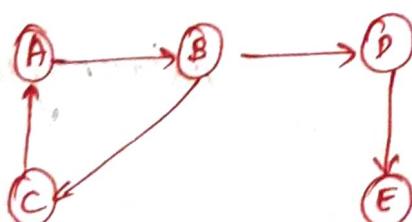

In directed graph, sum of lengths of all adjacency lists is equal to number of edges present in the graph.

### GRAPH TRAVERSAL ALGORITHM:

The graph is one non-linear data structure. That is consist of some nodes and their connected edges.

The edges may be directed or undirected. This graph can be represented as  $G(V, E)$ .

The following graph can be represented as  $G(\{A, B, C, D, E\}, \{(A, B), (B, D), (C, E), (B, C), (C, A)\})$

The graph has two traversal algorithms.

Breadth First Search

Depth First Search.

Breadth First Search (BFS)

BFS is a graph traversal algorithm that starts traversing graph from root node and explores all the neighbouring nodes.

Then it selects nearest nodes and explores all unexplored nodes.

The algorithm follows same process for each of nearest node until it finds goals.

Algorithm:

@TopperWorld

Step 1: SET STATUS = 1 (ready state)  
for each node in

Step 2: enqueue starting node A & set its status = 2 (waiting) state

Step 3: repeat step 4 and 5 until queue is empty

Step 4: Dequeue a node N, process it, set its STATUS = 3

Step 5: enqueue all neighbours of N that are in ready

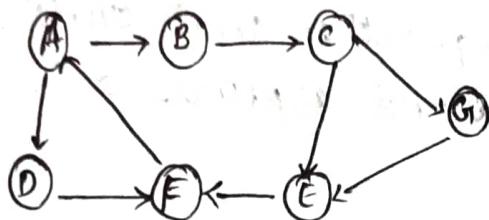

state (whose STATUS = 1) & set (STATUS = 2)

[END OF LOOP]

Step 6:  
Exit

### EXAMPLE

consider a graph shown in following image, calculate minimum path  $p$  from node A to node E given that each edge has length of 1

### Adjacency list

A : B, D

B : C, F

C : E, G

D : F

G : E

E : B, F

F : A

Solution: minimum path  $p$  can be found by applying Breadth First Search algorithm that will begin at node A and will end at node E

$$A \rightarrow B \rightarrow C \rightarrow E$$

### Depth First Search Algorithm:

DFS starts with initial node of graph  $g$  and goes deeper and deeper until we find goal node / node which has no children.

The Data structure used in DFS is stack.

### ALGORITHM:

step 1: SET STATUS = 1 (ready state) for each node in  $G$

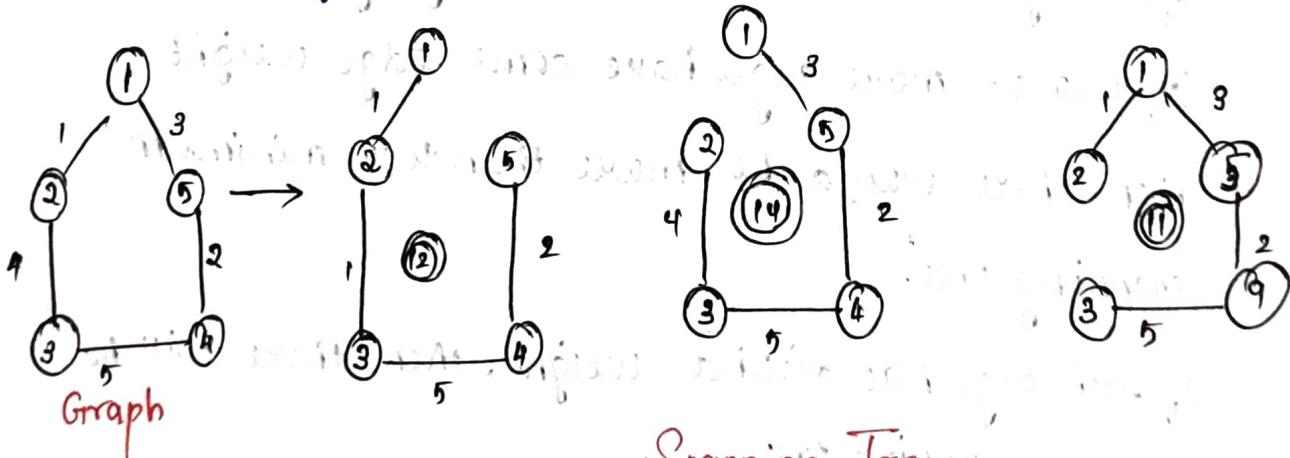

- step 2: push starting node A on stack & set its STATUS = 2 (waiting state)
- step 3: Repeat steps 4 and 5
- step 4: pop top node N, process it & set its STATUS = 3
- step 5: push on stack all neighbours of N that are in ready state (whose STATUS = 1) and set their STATUS = 2 (waiting state) [END OF LOOP]
- step 6: EXIT

### SPANNING TREE

If we have a graph containing  $v$  vertices and  $E$  edges, then the graph can be represented as  $G(v, E)$

If we create spanning tree from above graph then spanning tree would have some number of vertices as the graph, but vertices are not edges.

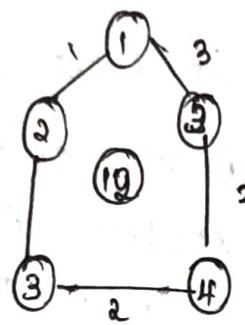

$$\text{spanning tree} = \text{no of edge (in graph)} - 1$$

Spanning Tree

## Minimum Spanning Tree:

The minimum spanning tree is a tree whose sum of edges weights is minimum.

In above tree, total edge weight less than above spanning tree, therefore a minimum spanning tree is a tree which is having an edge weight is 12.

## Properties of spanning Tree:

A connected graph can contain more than one spanning tree.

All possible spanning trees that can be created from given graph minus 1

spanning trees does not contain any cycle

If two or more edges have same edge weight then there would be more than two minimum spanning tree.

If each edge has distinct weight, then there will be only one spanning tree

## Applications of spanning tree:

Building a network: suppose there are many routers in a network connected to each other. so there might be a possibility that it forms a loop.

clustering- grouping set of objects in such a way that similar objects belongs to same group than to different group.

## SEARCHING:

There are two methods widely used:

Linear Search

Binary Search.

### ALGORITHM FOR LINEAR SEARCH.

LINEAR - SEARCH (A, N, VAL)

step1: [INITIALIZE] SET POS = -1

step2: [INITIALIZE] SET I = 1

step3: Repeat step 4 and 5

step4: If A[I] = VAL

SET POS = I

PRINT POS

GOTO STEP 6

[END OF IF]

PRINT POS

© TopperWorld

Goto step 6

[END OF IF]

SET I = I+1

[END OF LOOP]

step 5: If  $PDS = -1$

PRINT "VALUE is not present in array"

[END OF IF]

step 6: EXIT

### COMPLEXITY OF ALGORITHM:

Complexity	Best case	Average case	Worst case
Time	$O(1)$	$O(n)$	$O(n)$
Space			$O(1)$

### C PROGRAM

#### LINEAR SEARCH

```
#include <stdio.h>
void main()
{
    int a[10] = {10, 23, 40, 11, 2, 0, 14, 13, 50, 97};
    int item, i, flag;
    printf("Enter item which is to be searched in ");
    scanf("%d", &item);
    for(i=0; i<10; i++)
    {
        if(item == a[i])
        {
            flag = 1;
            break;
        }
    }
    if(flag == 1)
        printf("Item found");
    else
        printf("Item not found");
}
```

```

if (a[i] == pitem)
{
    flag = 1;
    break;
}
else
{
    flag = 0;
}

if (flag != 0)
{
    printf("The item found at location %d\n", i);
}
else
{
    printf("The item not found");
}

```

TopperWorld

Output:

Enter item which is to be searched:

20

Item not found

Enter item which is to be searched:

23

Item found at location 2.

## BINARY SEARCH

### ALGORITHM

BINARY - SEARCH (A, LOWER-bound, upper-bound, VAL)

Step 1: [INITIALIZE]. SET BEG = lower\_bound

END = upper\_bound, POS = -1

Step 2: Repeat steps 3 and 4 with  $BEG \leq END$

Step 3: SET MID =  $(BEG + END)/2$

Step 4: IF A[MID] = VAL

SET POS = MID

PRINT POS GO to step 6

ELSE IF A[MID] > VAL

SET END = MID - 1

ELSE SET BEG = MID + 1

Step 5: If POS = -1

PRINT "VALUE IS NOT PRESENT IN ARRAY"

Step 6: EXIT

### COMPLEXITY

SNO	PERFORMANCE	COMPLEXITY
1	WORST CASE	$O(\log n)$
2	BEST CASE	$O(1)$

- 3) Average case  $O(\log n)$
- 4) worst case  $O(1)$   
space complexity

Let us consider an array  $a = \{1, 5, 7, 8, 13, 19, 20, 23, 29\}$   
find location of item 23 in array

In 1st step

$$\text{BEG} = 0$$

$$\text{END} = 8$$

$$\text{MID} = 4$$

$$a[\text{mid}] = a[4] = 13 < 23 \text{ therefore}$$

In 2nd step

$$\text{Beg} = 5 \quad \text{mid} + 1 = 5$$

$$\text{End} = 8$$

$$\text{mid} = 13/2 = 6$$

$$a[\text{mid}] = a[6] = 20 < 23. \text{ therefore :}$$

In 3rd step

$$\text{Beg} = \text{mid} + 1 = 7$$

$$\text{End} = 8$$

$$\text{mid} = 15/2 = 7$$

$$a[\text{mid}] = a[7]$$

$$a[7] = 23 = \text{item}$$

$\therefore \text{SET LOCATION} = \text{mid.}$

location of item is 7

item to be searched = 23

Step 1	1	5	7	8	13	19	20	23	29
	0	1	2	3	4	5	6	7	8

Step 2	1	5	7	8	13	19	20	23	29
	0	1	2	3	4	5	6	7	8

Step 3	1	5	7	8	13	19	20	23	29
	0	1	2	3	4	5	6	7	8

In step 1:

$$a[\text{mid}] = 13$$

$$13 < 23$$

$$\text{beg} = \text{mid} + 1 = 5$$

$$\text{end} = 8$$

$$\text{mid} = (\text{beg} + \text{end}) / 2 = 13/2 = 6$$

@TopperWorld

In step 2:

$$a[\text{mid}] = 20$$

$$20 < 23$$

$$\text{beg} = \text{mid} + 1 = 7$$

$$\text{end} = 8$$

$$\text{mid} = (\text{beg} + \text{end}) / 2$$

$$= 15/2$$

$$= 7$$

Step 3

$$a[mid] = 23$$

$$23 = 23$$

$$\therefore loc = mid.$$

### C PROGRAM

#### BINARY SEARCH

```
#include <stdio.h>
int binarySearch(int[], int, int, int);
void main()
{
    int arr[10] = {16, 19, 20, 23, 45, 56, 78, 90,
                  96, 100};
    int item, location = -1;
    printf("enter item to search");
    scanf("%d", &item);
    location = binarySearch(arr, 0, 9, item);
    if (location != -1)
    {
        printf("Item found at location %d", location);
    }
}
```

```

    else
        printf ("item not found");
    }

}

int Binary Search (int a[], int beg, int end, int
                   item)

{
    int mid;

    if (end >= beg)
    {
        mid = beg + end / 2;
        if (a[mid] == item)
            return mid;
        else if (a[mid] < item)
            return binarySearch (a, mid + 1, end, item);
        else
            return binarySearch (a, beg, mid - 1, item);
    }
    return -1;
}

```

©TopperWorld

Output:

enter item to search

19

item found at location 2

## SORTING ALGORITHM

### BUBBLE SORT

#### ALGORITHM

begin BubbleSort (arr)

for all array elements

if arr[i] > arr[i+1]

swap (arr[i], arr[i+1])

end if

end for

return arr

end

bubble sort.

#### Bubble sort Complexity

MERGE (arr, beg, mid, end)

end of if

End MERGE-SORT

## IMPLEMENTATION OF MERGE SORT

void merge (int a[], int beg, int mid, int end)

{

int i, j, k;

int n<sub>1</sub> = mid - beg + 1;

int n<sub>2</sub> = end - mid;

int leftArray[n<sub>1</sub>], RightArray[n<sub>2</sub>] ;

for (int i=0; i < n<sub>1</sub>; i++)

leftArray[i] = a[beg + i]

for (int j=0; j < n<sub>2</sub>; j++)

RightArray[j] = a[mid+1+j];

i=0;

j=0;

k=beg;

79  
while ( $i < n_1$  &  $j < n_2$ )

{

if ( $\text{leftArray}[i] \leq \text{rightArray}[j]$ )

{

$a[k] = \text{leftArray}[i];$

$i++;$

}

else

{

$a[k] = \text{rightArray}[j];$

$j++;$

}

$k++$

}

while ( $i < n_1$ )

{

$a[k] = \text{leftArray}[i];$

$i++;$

$k++$

}

while ( $j < n_2$ )

{

$a[k] = \text{rightArray}[j];$

$j++;$

$k++$

}

}

## DATA STRUCTURE CODING QUESTION

### ① ARRAYS USING C:

Program to demonstrate arrays in c.

```
#include <stdio.h>
#include <windows.h>
#include <stdlib.h>
#define NUM_EMPLOYEE 10.
int main (int argc, char * argv[])
{
    int salary [NUM_EMPLOYEE], lcount=0, gcount=0, i=0;
    printf ("enter employee salary (MAX 10) \n");
    for (i=0; i<NUM_EMPLOYEE; i++)
    {
        printf ("In enter employee salary : .d -", i+1);
        scanf ("%d", &salary[i]);
    }
    for (i=0; i<NUM_EMPLOYEE; i++)
    {
        if (salary[i] < 3000)
            lcount++;
        else
            gcount++;
    }
    printf ("In There are %d employee with salary
more than 3000 \n", gcount);
```

```

printf("There are %d employee with salary less than
3000\n", lcount);
printf("press enter to continue...\n");
getchar();
return 0;
}

```

## ② linked list in c++:

```

using namespace std;
template < typename T>
class node
{
public;
T value;
Node * next;
Node * previous;
Node(T value)
{
    this->value = value;
}
};

template < typename T>
class linked list
{
private:
int size;
Node<T> * head = NULL;

```

©TopperWorld

```

Node<TY *tail = NULL;
Node<TY *ptr = NULL;
public:
Linked list()
{
    this->size = 0;
}

void append(TY value)
{
    if (this->head == NULL)
    {
        this->head = new Node<TY>(value);
        this->tail = this->head ->
    }
    else
    {
        this->tail ->next = new Node<TY>(value);
        this->tail ->next->previous = this->tail;
    }
    this->size += 1;
}

void append(TY value)
{
    void resetIterator()
    {
        tail = NULL;
    }
}

int main(Pnt arg c, char** arg v)
{
}

```

```
linked list <int> lList;  
lList.append(10);  
lList.append(13);  
cout << "printing linked list << ende";  
cout << endl;  
return 0;
```

## Stack implementation in c:

```
#include <stdio.h>  
  
int MAXSIZE = 8;  
int stack[8];  
int top = -1;  
  
int isempty() {  
    if (top == -1) {  
        return 1;  
    } else  
        return 0;  
}  
  
int isfull() {  
    if (top == MAXSIZE)  
        return 1;  
    else  
        return 0;  
}  
  
int peek() {  
    return stack[top];  
}
```

@TopperWorld

```

int pop() {
    Pnt data;
    if (!isempty()) {
        data = stack[top];
        top = top - 1;
        return data;
    }
    else {
        printf("could not retrieve data, stack is empty\n");
    }
}

int push(Pnt data) {
    if (!isfull()) {
        top = top + 1;
        stack[top] = data;
    }
    else {
        printf("could not insert data, stack is full\n");
    }
}

Pnt main() {
    // push items onto the stack
    push(3);
    push(5);
}

```

```

push(9);
push(1);
push(12);
push(15);
printf("elements at top of stack: %d\n", peek());
printf("elements : \n");
//print stack data.
while (!isEmpty()){
    int data = pop();
    printf("%d\n", data);
}
printf("stack is full: %s\n", isFull() ? "true" : "false");
printf("stack is empty: %s\n", isEmpty() ? "true" : "false");
return 0;
}

```

## DATA STRUCTURE INTERVIEW QUESTIONS:-

① What is a Data Structure:

A data structure is a logical way that data is organised within a program

② Why create Data Structures?

Data structures serve number of functions (important)  
in a program

③ what are some applications of data structure

Block chain

Database Design

Compiler Design

Genetics

Decision making

Numerical and statistical analysis

④ Describe types of data structure?

Linear Data Structure

Non-linear Data Structure

⑤ what are the different operations available in stack?

push

pop

top

isEmpty

size

⑥ what are the application of queue?

call management in call centres

Operating system: job scheduling, operations, CPU scheduling

⑦ what are the different operations available in deque?

enqueue

dequeue

isEmpty

clear

front

size

@TopperWorld

⑧ Difference b/w stack and Queue.

stack is based on LIFO

Queue is based on FIFO.

stack is used in solving recursion

Queue is used in sequential processing problems.

⑨ what are the methods available in storing sequential files?

straight merge

natural merge

polyphase sort

distribution of initial runs.

⑩ list out few of applications of tree data structure?

The manipulation of arithmetic expression, symbol table construction & syntax analysis

⑪ How to check whether linked list is circular?

create two pointers, each set to start of list

update each as follows:

while(pointer)

{

pointer 1 = pointer 1 → next;

pointer 2 = pointer 2 → next;

if (pointer 2) pointer 2 = pointer 2 → next;

if (pointer1 == pointer 2)

{

print ("circular")

}

}

⑫ List the basic Operations carried out in linked list?

creation of list

Insertion of list

deletion of list

modification of node

Traversal of node

(13) List out the basic operations that can be performed on stack.

push

pop

peek

empty

fully occupied.

(14) State the different ways of representing expression

Infix notation

prefix notation

postfix notation

(15) what is sequential search?

The sequential search each item in the array is compared with item being searched until a match occurs

(16) what are the different types of linkedlist?

Singly linked list

doubly linked list

circular linked list
